Jeeraprapa Siriwaseree : Comparative S-FTIR Analysis of JAK Inhibitors in TF-1 Cells and Evaluation of Kerra™ Extract for HCT116 Colon Cancer. Doctor of Philosophy (Biochemistry), Major Field: Biochemistry, Department of Biochemistry.

Thesis Advisor: Associate Professor Kiattawee Choowongkomon, Ph.D.  
Academic Year 2024

This dissertation comprises two distinct research inquiries. The first inquiry analyzes the chemical signatures of TF-1 cells post JAK inhibitor treatment, specifically Ruxolitinib and Tofacitinib, using S-FTIR spectroscopy. JAK pathway deregulation is associated with myelofibrosis pathogenesis. Ruxolitinib demonstrated superior inhibitory efficacy over Tofacitinib, which targets JAK3. PCA successfully differentiated untreated and drug-treated cells, revealing biochemical changes in cellular components. The results affirm FTIR's efficacy in investigating drug-induced molecular changes, emphasizing JAK inhibitors' unique effects on cellular elements. The second investigation examines Kerra™, a botanical extract from the Takxila scripture, on HCT116 colorectal cancer cells. This study evaluated the extract's effects on cancer cell viability and apoptosis through various assays. Apoptotic protein marker levels were quantified and elucidated the extract influenced the proteins and pathways by proteomics analysis. Kerra™ extract demonstrated a dose-dependent cytotoxicity, with higher concentrations leading to reduced cell viability in a 72-hour treatment period plus revealing early-late apoptosis characteristics. LC-MS/MS analysis identified 3,406 proteins. Pathway analysis indicated that Kerra™ extract induced apoptotic signaling and inhibited proliferation in cell lines via the EIF2 pathway. Regulatory proteins, including CDKN1A and MYC, were identified. Importantly, caspase 8 and 9 expression levels significantly increased in response to Kerra™ compared to Doxorubicin. These findings strongly support the extract's ability to induce apoptosis in HCT116 colon cancer cells. Its efficacy was confirmed through its dose-dependent cytotoxicity, apoptotic induction, and modulation of key proteins in death and proliferation pathways. This research highlights Kerra™'s potential as a promising therapeutic entity in cancer treatment.

## ACKNOWLEDGEMENTS

I am immensely grateful to Associate Professor Dr. Kiattawee Choowongkomon for allowing me to pursue my doctoral program. His extensive knowledge, expertise, and encouragement were invaluable and greatly contributed to the success of my thesis. I also appreciated my co-advisor, Dr. Buabarn Kuaprasert, for the support and respected guidance provided to me as I worked on the thesis and related publications. This achievement would not have been possible without the support of the Royal Golden Jubilee Ph.D. Program between the National Research Council of Thailand (NRCT) and the Synchrotron Light Research Institute (SLRI) (Grant no. PHD/0137/2561). Furthermore, I wish to express my gratitude for the valuable comments and feedback provided by the defense committees, which were instrumental in the successful completion.

I also express my sincere gratitude to Associate Professor Dr. Panan Kanchanaphum for his invaluable tutoring and support, particularly for facilitating my introduction to my advisor which enabled me to pursue my doctoral studies. I am deeply appreciative of the knowledge and guidance provided by my teachers. Additionally, I am thankful to my colleagues at KC lab, especially Dr. Siriluk Ratanabunyong, for their collaborative efforts, constructive feedback, and moral support during early-morning and late-night work sessions. I am also grateful to the research assistants, scientists, and officers from the Department of Biochemistry for their assistance and support.

Finally, I would be remiss in not mentioning my family, particularly my parents and siblings, for their unwavering support. Their constant belief in my abilities provided the encouragement and resilience necessary to persevere through favourable and adverse circumstances. Their influence has prevented despondency and steering me towards accomplishment.

Jeeraprapa Siriwaseree

## **Comparative S-FTIR Analysis of JAK Inhibitors in TF-1 Cells and Evaluation of Kerra™ Extract for HCT116 Colon Cancer**

### **SCOPE/STRUCTURE OF STUDY**

This project contains two studies including the Janus kinase (JAK) inhibitor's effects on TF-1 myelofibrosis cancer cells and the apoptotic effects of the Kerra™ extract on HCT116 colorectal cancer cells.

The research paper titled "Synchrotron Fourier Transform Infrared Microscopy Spectra in Cellular Effects of Janus Kinase Inhibitors on Myelofibrosis Cancer Cells" aims to assess the chemical changes in cells following treatment with JAK inhibitors, shedding light on their potential for myelofibrosis therapy. The study utilizes synchrotron Fourier transform infrared (S-FTIR) spectroscopy to delve into the molecular-level impacts of these drugs on cellular biochemical components. By employing a fingerprint approach that combines S-FTIR data with in vitro cytotoxicity assays, the research unveils distinct patterns of cellular responses to the JAK inhibitors. The comparison of two inhibitors, Ruxolitinib and Tofacitinib, reveals that Ruxolitinib has a more pronounced inhibitory effect on TF-1 cells. Furthermore, the study involves calculating IC<sub>50</sub> values and utilizing principal component analysis (PCA) to categorize cellular biochemical alterations under different treatment conditions. The research sheds light on the molecular changes induced by JAK inhibitors on TF-1 myelofibrosis cancer cells using advanced spectroscopic techniques, aiming to enhance understanding of their biochemical impacts and therapeutic potential.

The second publication was titled "Exploring the Apoptotic-Induced Biochemical Mechanism of Traditional Thai Herb (Kerra™) Extract in HCT116 Cells Using a Label-Free Proteomics Approach". This study delves into the mechanisms through which the Kerra™ extract triggers apoptosis in the HCT116 colorectal cancer cell line. It investigates the effects of the Kerra™ extract on cell viability and apoptosis in a dose-dependent manner. Additionally, the research aims to understand the biochemical mechanisms that regulate apoptotic markers such as caspase-8 and

caspase-9. The study utilizes a label-free proteomics approach to analyze changes in protein expression, shedding light on the molecular mechanisms and pathways impacted by the Kerra™ extract. These articles form an integral part of my graduation thesis.

## INTRODUCTION

Cancer is the rapid creation of abnormal cells that grow from the transformation of normal cells into tumor cells. In general, cancer progresses from a pre-cancerous lesion to a malignant tumor that grows beyond and can invade bordering parts of the body and spread to other organs referred to as metastasis. Metastases are the main cause of death from cancer. These changes are the result of the interaction between a person's genetic factors and external agents. Global cancer statistics 2018: GLOBOCAN estimates of incidence and mortality worldwide for 36 cancers. In both sexes combined, lung cancer is the most diagnosed cancer (11.6% of the total cases) and the leading cause of cancer death (18.4% of the total cancer deaths), closely followed by female breast cancer (11.6%), the most commonly diagnosed cancer and the leading cause of cancer death [1].

The treatment to treat and manage cancer is available. The effectiveness of the treatment depends on the type of cancer, the location of the tumor, and the stage of its progression. Some traditional and widely used treatment options include surgery, radiation-based surgical knives, chemotherapy, and radiotherapy. Although chemotherapy is commonly used, it often comes with side effects. However, these treatments have not been able to significantly improve mortality rates or prolong survival time for metastatic cancer. In addition, drugs, biological molecules, and immune-mediated therapies are now being used for treatment.

New medications that target specific tumor pathways and characteristics are being researched to create a revolution in cancer treatment [2]. For instance, JAK inhibitors are a class of drugs that target the JAK/STAT signaling pathway which is the dysregulated cell signaling pathway that leads to tumor growth. Preclinical has shown tumor inhibition results, enhanced therapies' effects, and treating solid tumors in several clinical trials [3-5]. Nevertheless, some inhibitors found side effects and adverse events associated with infectious events among patients using these medications [6, 7]. Therefore, finding alternative methods that are more effective and less toxic is necessary. Traditional medicine is the first line of treatment that relies on the concern about the synthetic drug's safety and efficacy.

Natural products are increasingly identified as sources of pharmacological drugs and are used to treat various diseases, including cancers and neurological disorders [8].

The development of dependable and inexpensive technologies for the screening of individuals with cancer, for improving the early diagnosis of cancer and the prediction of treatment, and for prevention activities to reduce the incidence of cancer. For this reason, cancer biomarkers and molecular changes are important for discovering and validating cancer research [9]. The FTIR is a powerful tool for the study of biological systems. Its spectroscopy can consider molecular changes in cells exposed to antitumor drugs based on the S-FTIR spectrum [10]. Likewise, Proteomics analysis has become critical in biological alternated investigation. This technology has identified information, including protein targets and signaling pathways associated with cancer cell growth and cellular response.

### **Background and Rationale**

First publication, JAKs are intracellular tyrosine kinases that play a crucial role in signal transduction for cytokines and growth factors via the JAK/STAT pathway. Dysregulation of JAKs can result in cancer and autoimmune diseases. Specifically, JAK2 mutations have been associated with myelofibrosis, a form of bone marrow cancer. Therefore, the inhibition of JAK2, such as with Ruxolitinib and Tofacitinib, is an important therapeutic option. Ruxolitinib selectively inhibits JAK1 and JAK2, while Tofacitinib is more specific to JAK3. Understanding the distinct mechanisms of these inhibitors is essential for optimizing treatment strategies for myelofibrosis. In this study, S-FTIR spectroscopy is used to analyze molecular changes in cancer cells following drug treatment, providing insights into the chemical fingerprints of cells and their responses to drugs. Previous research has shown that FTIR spectroscopy is effective in evaluating drug sensitivity in cancer cells and interactions of molecular components with anti-cancer drugs. This study aims to explore the specific effects of JAK inhibitors on TF-1 cells and to better characterize the impact of JAK2 inhibition, offering insights into the differing clinical effectiveness of the two drugs.

In the second publication, recent studies have shown a growing interest in utilizing natural products for cancer treatment due to their ability to impact multiple

pathways involved in cancer cell growth. This approach has shown promise in identifying new potential drugs that may be more effective than single compounds targeting specific markers. Specifically, the research emphasizes the importance of traditional herbs, such as the Kerra™ extract, which is a combination of various medicinal plants known for their potential in cancer treatment. Despite its historical use, there is a significant gap in our understanding of its efficacy and the mechanisms through which it affects cancer cells. Inducing apoptosis (cell death) in cancer cells is a crucial therapeutic strategy. Therefore, the study aims to investigate how the Kerra™ extract triggers this process in colon cancer cells through proteomics analysis. This method allows for a comprehensive exploration of protein changes in response to the Kerra™ extract, shedding light on the extract's effects on apoptosis and other cellular processes. This research underscores the potential of traditional medicine in providing effective and low-side-effect cancer treatments as an alternative to conventional therapies. By elucidating the apoptotic mechanisms induced by the Kerra™ extract, the study seeks to contribute to the development of safe and efficient cancer therapies.

### **Objectives**

1. To evaluate the effects of JAK inhibitors, specifically Ruxolitinib and Tofacitinib, on erythroleukemia TF-1 cell line by S-FTIR spectroscopy.
2. To investigate how the Kerra™ extract induces apoptosis in HCT116 cells by exploring the biochemical pathways and mechanisms using proteomics.

### **Contributions and Outcome of Research**

The first article successfully assessed the chemical fingerprints of TF-1 cells after treatment with Ruxolitinib and Tofacitinib using S-FTIR spectroscopy. Based on PCA can classify the biochemical alterations in treated versus untreated cells. It identified significant changes in lipid production, protein conformation, and nucleic acid levels, indicating how these inhibitors modify cellular biochemistry. These allowed for the identification of distinct molecular changes in response to the drugs, contributing to the understanding of their mechanisms of action. The findings suggest that FTIR spectroscopy can be a valuable tool for analyzing cellular responses

to drug treatments at the molecular level. The differences in the effectiveness of Ruxolitinib and Tofacitinib were found that Ruxolitinib had a two-fold higher inhibition effect on TF-1 cell lines compared to Tofacitinib. Ruxolitinib and Tofacitinib modulate the JAK/STAT signaling pathway that is shown to decrease STAT3 phosphorylation and induce apoptosis. This opens a broader understanding of myelofibrosis treatment and may help in developing more effective therapeutic strategies tailored to individual patient needs.

The second article indicated that the Kerra™ extract induced a higher level of late apoptosis and cell death compared to Doxorubicin (Dox) at IC<sub>50</sub> concentration. The extract can activate apoptosis and suppress cell proliferation in HCT116 cells through the EIF2 signaling pathway. This finding is crucial as it elucidates the specific pathways involved in the apoptotic process triggered by the extract. The study identified 3406 proteins affected by the Kerra™ extract in cell lines. CDKN1A and MYC were predicted as upstream regulators in response to the Kerra™ extract. This extensive proteomic analysis provides a comprehensive overview of the biochemical changes induced by the extract, highlighting its potential as a therapeutic agent for colon cancer and understanding these regulatory proteins can help in developing targeted therapies that enhance the efficacy of the extract in inducing apoptosis in cancer cells.

### Abstract

Janus kinases (JAKs) deregulation of the JAK/STAT pathway leads to myelofibrosis that can be treated by JAKs inhibitors including Ruxolitinib and Tofacitinib. Even though both inhibitors are effective against myelofibrosis, each of them has a different mode of action in the cells. Ruxolitinib is an inhibitor for selective JAK1/2 and Tofacitinib is an inhibitor for JAK3. This study evaluated the chemical fingerprints of TF-1 cells after JAKs inhibitor treatments by the Synchrotron Fourier transform

infrared microspectroscopy (S-FTIR) spectrum. Tofacitinib and Ruxolitinib treatments in TF-1 cells were applied with a chemical fingerprints approach in S-FTIR spectroscopy and in vitro cytotoxicity in a cell-based assay. Principal component analysis or PCA was utilized to classify three cell treatments with three biochemical alteration absorbances of lipids vibration by C-H stretching, protein amide I arise from C=O stretching, and P=O phosphodiester bond from nucleic acids. The results showed that the inhibition effect of Ruxolitinib on the TF-1 cell lines was two-fold higher than Tofacitinib. PCA distinguishes untreated and drug treatment by detected cellular biochemical alteration. The loading plots identify protein and nucleic acids were the different main components in disparate cell treatments. Tofacitinib separated from the others in lipid and nucleic acid. The second derivative spectra of three molecular components had decreased lipid production and accumulation, changes in secondary structures in proteins, and a high level of RNA overexpression in cell treatment. The JAKs inhibitors caused different spectroscopic biomarkers of the modifications of secondary protein conformation, stimulated cell lipid accumulation, and phosphorylation from untreated cells. The alteration of cellular biochemical components advises that the FTIR is a potential tool for used analyzing specific patterns of drug cellular responses at the molecular level.

## Introduction

Janus kinases (JAKs) are intracellular and nonreceptor tyrosine kinases family including, JAK1, JAK2, JAK3, and tyrosine kinase 2 (TYK2) that play signal transductions due to cytokines and growth factors<sup>1</sup>. These kinases are intermediaries between signal induction of cytokine and transcriptional factor phosphorylation, signal transducers and activators of transcription (STAT) passing through the JAK/STAT pathway. Therefore, JAK/STAT pathway deregulation can initiate cancer inflammation, and autoimmune diseases<sup>2,3</sup>.

JAK1 related to mutated sites has been associated with acute leukemia or B-cell lymphoma. JAK2 mutation is also allied with thrombocytosis, myelofibrosis, leukemia, and lymphoma, and JAK3 signaling increasing can develop T-cell acute lymphocytic leukemia<sup>2,4</sup>. The tyrosine kinase domain location is in the JH1 domain at the C-terminal of the JAKs. This domain is controlled through a pseudokinase domain or JH2 that lacks Asp residue for phosphotransfer in the His/Arg/Asp motif of the catalytic loop in kinase activity. Hence, this domain is assumed to regulate the JH1 domain catalytic activity<sup>5</sup>. Among the JAKs, JAK2 is a critical target for the treatment of cancer disease. JAK2 inhibition can decrease the risk of bone marrow cancer due to the prevention of JAK2 activation.

Myelofibrosis cancer can be treated by JAKs inhibition<sup>6</sup>. Ruxolitinib and Tofacitinib are two FDA-approved drugs that widely used in clinical treatment of this cancer. These drugs interact in the ATP site of the JAKs and prevent JAKs activation. As a result, signal transduction cannot occur, and the risk of this cancer is decreased. Ruxolitinib is selective for JAK1/2 (The half-maximal inhibitory concentration ( $IC_{50}$ ) for JAK1 = 3.3 and for JAK2 = 2.8 nM)<sup>7</sup>, whereas Tofacitinib is more selective for JAK3 ( $IC_{50}$  = 34 nM) than JAK1/2 ( $IC_{50}$  = 81 and 80 nM, respectively)<sup>8</sup>. Ruxolitinib is effective for JAK1/2 inhibition, whereas Tofacitinib can inhibition of JAK1/3 more than JAK2. It is an interesting approach to investigate the binding pattern of both drugs with JAKs.

The FTIR is an effective tool for studying the biological systems by considering the effect of molecular changes in cells on antitumor drugs based on the FTIR spectrum<sup>9</sup>. Numerous FTIR chemical fingerprints between cancer cells and

drugs have been reported. The leukemic cell lines (K562) treated with an Akt1/2 kinase inhibitor (A6730) showed a noticeable change in the  $\alpha$ -helix/ $\beta$ -strand conformation ratio<sup>10</sup>. A previous report revealed the capability of FTIR spectroscopy can evaluate the drug sensitivity in cells as well as interactions of different molecular components of anti-cancer drugs<sup>11</sup>. TF-1 cell line that originated from erythroleukemia in humans. These cells' proliferative are responsive to granulocyte-macrophage colony-stimulating factor (GM-CSF) or interleukin-3 (IL-3) through with JAK2/STAT signaling pathway activation<sup>12</sup>. Understanding the different inhibition patterns of drugs resulting from JAK2, based on the FTIR spectrum in cells treated with drugs, is important to better characterize the effect of JAK2 inhibition and the potential explanation for differences in clinical effectiveness.

In this study, the objective was to assess the chemical fingerprints of TF-1 cells after Tofacitinib and Ruxolitinib treatments. To achieve this, we applied a chemical fingerprints approach, using knowledge of both drugs in S-FTIR spectroscopy and *in vitro* cytotoxicity in a cell-based assay. These findings can be proposed that S-FTIR can be used for analyzing distinct patterns of cellular responses when drug-treated at the molecular level.

## Results

### 3.1 Effect of Ruxolitinib and Tofacitinib on the TF-1 cell lines

We used the TF-1 cells to investigate the dose dependence of drug treatment using the Presto Blue assay. At 72 h, the IC<sub>50</sub> of Ruxolitinib was  $14.47 \pm 0.59 \mu\text{M}$  and Tofacitinib was  $30.29 \pm 1.98 \mu\text{M}$  on TF-1 cells (**Figure 1**). These results showed that drugs can inhibit the viability of TF-1 cells, the inhibitory effect indicated that Ruxolitinib can inhibit TF-1 cells more than two-fold higher than Tofacitinib. However, the effect of both drugs on the TF-1 cells was further evaluated to consider molecular changes in cells by FTIR spectrum analysis.

**Figure 1** TF-1 cells viability after treatment with Ruxolitinib and Tofacitinib at various concentrations.

### 3.2 Molecular Docking

To demonstrate the interaction and binding mode of known drugs (Ruxolitinib and Tofacitinib) with JAK1 and JAK2, both compounds were individually docked into the binding pocket of the JAK1 and JAK2 proteins by using GOLD docking. The docking scores of Ruxolitinib in complex with both proteins (59.40 kcal mol<sup>-1</sup> for JAK1 and 57.81 kcal mol<sup>-1</sup> for JAK2) were higher than Tofacitinib (50.91 kcal mol<sup>-1</sup> for JAK1 and 51.88 kcal mol<sup>-1</sup> for JAK2) (**Figure S13**). From these results confirmed the previously reports that the Ruxolitinib strongly interact with JAK1 than JAK2 whereas Tofacitinib strongly interact with JAK2 than JAK1. Moreover, the binding pattern and 2D interactions of all systems are illustrated in **Figure 2**. We found Ruxolitinib and Tofacitinib bound at the binding site with a similar pattern to JAK1/2; both compounds bound well with the deazapurine ring and stabilized through other interactions such as Pi-sulfur, Pi-alkyl, Pi-sigma, and van der Waals (**Fig. S14 and S15**). Both drugs to be effective with JAK1 or JAK2 depending on the binding interactions and binding position inwards these proteins. The Glu957

and Leu959 are important interactions in the hinge region of JAK1<sup>13</sup>, this interaction is determined to be important for the binding of inhibitors within the kinase protein. Therefore, Ruxolitinib strongly binding with JAK1 than Tofacitinib via the formation of two strong hydrogen bonds. Moreover, the Glu930 and Leu932 residues in the hinge region that are unique to JAK2<sup>14</sup>, we found Ruxolitinib strongly binding with JAK1 than Tofacitinib via the formation of three strong hydrogen bonds.

**Figure 2** 2D interactions of Ruxolitinib and Tofacitinib complexed with (A and B) JAK1, and (C and D) JAK2.

### 3.3 FTIR analysis

To further investigate if the different mode of actions between both drugs could affect in inhibit the cell differently, the FTIR was used to see differences in the biochemical cell responses. The overall FTIR spectrum was obtained from whole-cell lines between wavelength lengths 3,800-1,000  $\text{cm}^{-1}$  in **Figure 3A**. The selected peaks at 2,923  $\text{cm}^{-1}$ , 1,656  $\text{cm}^{-1}$  and 1,238  $\text{cm}^{-1}$  were assigned to C–H stretch, C=O stretch, and P=O stretch, respectively<sup>15</sup>. The selected spectral groups were adjusted using third polynomial order, eleven smoothing points, and linear baseline correction for finished Savitzky–Golay smoothing converted to second derivatives and EMSC by Unscrambler X 10.4. For an additional detailed comparison between different cell treatments, these average spectra were analyzed by PCA.

### 3.4 PCA distinguishes untreated and drugs treatment by detected cellular biochemical alteration

The goal was to distinguish the different cell treatments with biochemical alteration by PCA. PCA is a dimensionality-reduction method that uses multivariate exploratory analysis techniques allowing identification of the significant variables or wave numbers describing differences between samples. PCA could be achieved and represented two types of information including plot scores indicating class separation and loading plots for identification of the variables providing for clustering the responsible information<sup>15</sup>. The 2D score plots in **Figure 3B** distinctly show the three samples; PC-1 was sufficient to separate the TF-1 drug treatment from the untreated cells with an accuracy of 83% while PC-2 explained 5% total variance in the model. From **Figure 3C**, the loading plots identify various biochemical components by PC-1 and PC-2. The major components in the different treatment cells were differentiated at around 1,700-1,500  $\text{cm}^{-1}$  for protein; it was reported that JAKs inhibitor-treated cells compared to untreated cells by PC-1 had higher signals amide I<sup>16</sup>. Previous research indicated that the range was around 3,000–2,800  $\text{cm}^{-1}$  for  $\text{CH}_2$  and  $\text{CH}_3$  asymmetric/symmetric stretching in lipids, fatty acids, and proteins, and 1,300-1,000  $\text{cm}^{-1}$  for  $\text{PO}_2^-$  asymmetric stretching of DNA and RNA in PC-2<sup>17</sup>. PC-2 loading scores showed Tofacitinib separated from the others with less lipid and a

higher level of nucleic acid accumulation. For further detailed analysis, the secondary derivative spectra were created and overlapped for comparison.

**Figure 3** (A) The average absorbance FTIR spectra of TF-1 cells in untreated conditions (blue), Tofacitinib treated cells (red), and Ruxolitinib treated cells (green). (B) Two-dimensional PCA score plot in PC1-2. (C) PCA corresponding loading plot PC1-2 indicating all samples biomarker differentiation.

### 3.5 Cellular biochemical identification and differentiation detected by the S-FTIR

The average FTIR absorbance spectra of three samples were subsequently transformed to a second derivative to reduce baseline slopes and cover every single band in the unrefined spectra of samples. To identify the band and sub-band components, the spectra after the second derivative process of three major molecular components including lipid, protein, and nucleic acid are presented in **Figures 4-6**. The peak areas were assigned to the molecular vibrations in individual wavenumbers or IR frequencies that are summarized in **Table 1**.

#### 3.5.1 FTIR spectra of treated cell display lipid alteration

The spectra in the region of 3,000–2,800  $\text{cm}^{-1}$  detected vibrations of the C-H groups  $\text{CH}_2$  in lipids and  $\text{CH}_3$  from fatty acids, lipids and proteins using symmetric/asymmetric parameters. The average of three samples second derivative spectra exhibited high absorbance at 2,963 2,923 and 2,852  $\text{cm}^{-1}$  (**Figure 4**). Untreated cells were stronger than the others for high lipid accumulation. After treatment with Tofacitinib and Ruxolitinib, the result was clearly observed indicating that both drug treatment decreases lipid production and accumulation. However, the absorbance of C-H symmetric stretching of  $\text{CH}_3$  at 2,874  $\text{cm}^{-1}$  was increased after drugs treatment.

**Figure 4** The average of second derivative FTIR spectra characterize lipid regions in the wavelengths from 3,000 to 2,800  $\text{cm}^{-1}$  of 60 spectra of untreated TF-1 cells (blue), 100 spectra of cells treated with 30.28  $\mu\text{M}$  Tofacitinib (red), and 42 spectra of cells treated with 14.47  $\mu\text{M}$  Ruxolitinib (green) after incubation for 72 h.

### 3.5.2 FTIR spectra display treated cell changes of secondary structures in proteins.

The most apparent measurable differences of second derivatives are that they were surrounded by reflecting vibrations of protein amide I in 1,700–1,600  $\text{cm}^{-1}$  (**Figure 5**). The major absorptions of the amide I band from C=O stretching of the backbone, and the peptide backbone vibrations of the N-H bending, and C-N stretching were detected and assigned vibrations revealing the secondary structures changing in proteins. On this basis, infrared bands in the 1,660–1,650  $\text{cm}^{-1}$  were defined to be the  $\alpha$ -helices structure,  $\beta$ -sheets imposed in the wavelengths 1,640–1,620  $\text{cm}^{-1}$ , in the 1,695–1,660  $\text{cm}^{-1}$  region, determined to be  $\beta$ -turns and  $\beta$ -sheets structures. Furthermore, 1,650–1,620  $\text{cm}^{-1}$  region to unordered structures<sup>16, 18</sup>. All the sample results showed that the absorption peaks appeared  $\alpha$ -helix (1,656  $\text{cm}^{-1}$ ) and  $\beta$ -sheet (1,639  $\text{cm}^{-1}$ ) in the amide I. Although Tofacitinib and Ruxolitinib treated cells had remarkably reduced  $\alpha$ -helices absorbance and an increase in the  $\beta$ -sheet peak at

1,639-1,633  $\text{cm}^{-1}$ . Particularly, the aggregated peak at 1,630-1,620  $\text{cm}^{-1}$  was increased in Tofacitinib treated cells. This implies that the intramolecular  $\beta$ -sheet structures collapsed into aggregated forms.

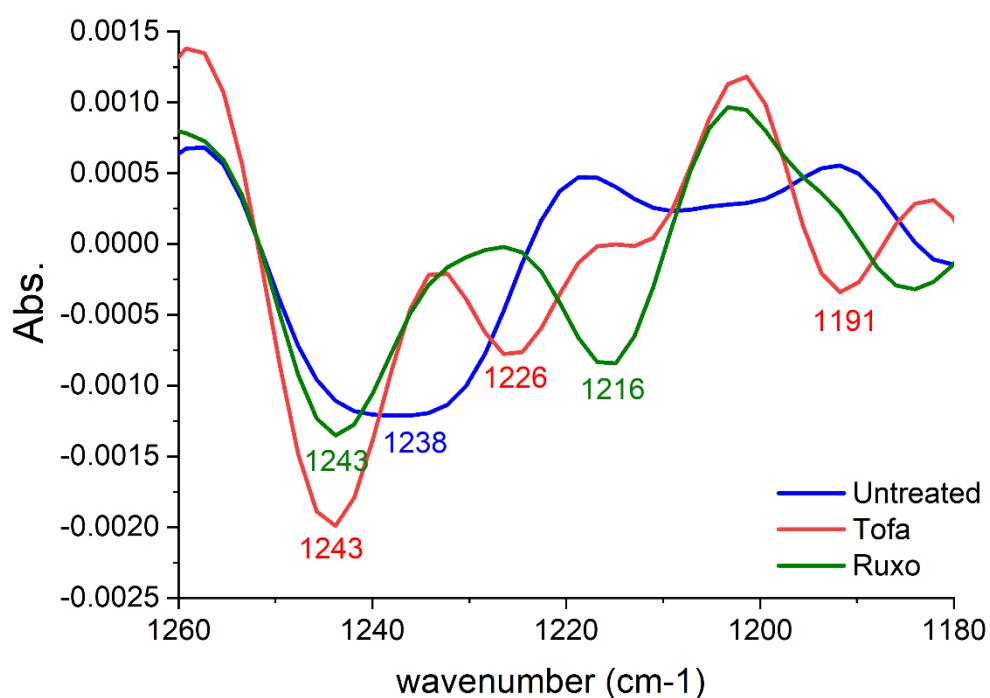

**Figure 5** Average second derivative FTIR spectra characterize protein regions in wavenumbers from 1,700 to 1,600  $\text{cm}^{-1}$  of 60 spectra of untreated TF-1 cells (blue), 100 spectra of Tofacitinib treated (30.28  $\mu\text{M}$ ) cells (red), and 42 spectra of Ruxolitinib treated (14.47  $\mu\text{M}$ ) cells (green) after incubation for 72 h.

### 3.5.3 High level of RNA overexpression in cell treatment

Average second derivative FTIR spectra characterizing nucleic acid regions in wavenumbers from 1,300 to 1,000  $\text{cm}^{-1}$  are shown in **Figure 6**. Treated cells exhibited high synthesized nucleic acid levels at 1,243-1,238  $\text{cm}^{-1}$  peaks together with 1,226-1,216  $\text{cm}^{-1}$  related to asymmetrical stretching of  $\text{PO}_2^-$  in the phosphodiester backbone of DNA or RNA; also, the high absorption of amide III band region at 1,191  $\text{cm}^{-1}$ . In previous publications, the FTIR application establishes biomarkers for early screening of B-cell precursor lymphoblastic leukemia (BCP-ALL). The control group peak area at 1,241  $\text{cm}^{-1}$  was identified as asymmetric/symmetric stretching of

PO<sub>2</sub><sup>-</sup> (nucleic acids, phosphorylated proteins, and phospholipids)<sup>19</sup>. This correlates with the peak result of the treated cells which exhibited high synthesized nucleic acid levels at 1,243-1,238 cm<sup>-1</sup>. As a result of both type I inhibitor effect mechanisms, Ruxolitinib decrease signaling can be associated with the accumulation of activation loop phosphorylation for preventing JAK2 dephosphorylation and ubiquitination<sup>20</sup>.

**Figure 6** Average second derivative FTIR spectra characterize nucleic acids regions in wavelength from 1,300 to 1,000 cm<sup>-1</sup> of 60 spectra of untreated TF-1 cells (blue), 100 spectra of 30.28 μM of Tofacitinib treated cells (red), and 42 spectra of 14.47 μM Ruxolitinib treated cells (green) after incubated for 72 h.

**Table 1** The second derivative FTIR spectra band assignments for the vibration of functional groups that are found in untreated and drug-treated TF-1 cells.

Regions	Second derivative spectra (cm <sup>-1</sup> ) band	Band assignments
Lipid	2,963	C-H asymmetric stretching (CH <sub>3</sub> ) in fatty acids, lipids, and proteins <sup>17</sup>
	2,923	C-H asymmetric stretching (CH <sub>2</sub> ) in fatty acids, lipids, and proteins <sup>17</sup>
	2,874	C-H symmetric stretching (CH <sub>3</sub> ) in fatty acids, lipids, and proteins <sup>17</sup>
	2,852	C-H symmetric stretching (CH <sub>2</sub> ) in fatty acids, lipids, and proteins <sup>17</sup>
Protein	1,656-1,650	α-helix structure of amide I <sup>17</sup>
	1,639-1,633	β-sheet structure of amide I <sup>17</sup>
Nucleic acid	1,243-1,238	PO <sub>2</sub> <sup>-</sup> asymmetric and symmetric stretching (phosphate I) (nucleic acids, phosphorylated proteins, and phospholipids) <sup>17, 19</sup>
	1,226-1,216	PO <sub>2</sub> <sup>-</sup> asymmetric stretching (phosphate I) <sup>17</sup>
	1,191	Amide III band region <sup>17</sup>

## Discussion

The JAK-STAT pathway is related to cellular processes such as cell division, proliferation, cell death, tumor formation, and immunity. The pathway information from chemical signals outside to the nucleus of the cell, results in the initiation of genes through a process called transcription<sup>21</sup>. Ruxolitinib and Tofacitinib **are first-generation and type I kinase inhibitors, which competitively** ATP binding site and represses the enzyme activity of JAK kinases, thus the effect of inhibitors is silencing the signal transduction and action of cytokine. As a result, signal transduction cannot occur, and the risk of this cancer is decreased. Therefore, FTIR is an effective tool that can study biological systems and consider the molecular changing of cells, subjected to antitumor drugs based on the FTIR spectrum<sup>9</sup>.

This study, evaluate the chemical fingerprints of TF-1 cells after Tofacitinib and Ruxolitinib treatments. The TF-1 cells are proliferative responses to IL-3 or GM-CSF that can result in activation of the JAK2/STAT signaling pathway. Both JAKs inhibitor drugs are selective JAK inhibitors but Ruxolitinib is effective for JAK1/2 inhibition, whereas Tofacitinib causes a higher inhibition of JAK1/3 than JAK2<sup>22</sup>. This result corresponds to the higher inhibition of TF-1 cells by Ruxolitinib than Tofacitinib.

From the binding mode analyzed of known drugs (Ruxolitinib and Tofacitinib) with JAK1 and JAK2, we found that the docking scores of Ruxolitinib in complex with both proteins were higher than Tofacitinib (**Supplemental data figure 13**). These results suggested that Ruxolitinib fits better with both proteins than Tofacitinib due to the fact that Ruxolitinib is a dual inhibitor against JAK1/2, whereas Tofacitinib is a dual inhibitor for JAK1/3<sup>23</sup>. Additionally, 2D interactions and the binding pattern bound well with the deazapurine ring at the ATP-binding site (**Supplemental data figure 14**). In JAK1, the nitrogen atoms on the deazapurine ring of Ruxolitinib formed two hydrogen bonds (H-bonds) with Glu957 and Leu959, while Tofacitinib formed H-bonds with Leu959. For JAK2, we found that nitrogen atoms on the deazapurine ring and nitrile group formed H-bonds with Lys882, Glu930, Leu932 for Ruxolitinib and Leu932, Arg980 for Tofacitinib (**Figure 2**). Apart from that, all compounds are stabilized through other interactions such as Pi-sulfur, Pi-sigma, Pi-

alkyl and van der Waals interaction; these interactions are called hydrophobic interactions (**Supplemental data figure 15**)

The goal was to evaluate the chemical fingerprints of TF-1 cells after Tofacitinib and Ruxolitinib treatments. FTIR analysis was performed and determined from the absorption (or transmission) versus wavelength (or frequency) of infrared radiation associated with vibrations of functional groups within the molecule, and chemical bonds between atoms undergoing various forms<sup>24</sup>. The second derivative spectra of three major molecular components including lipid, protein, and nucleic acid are presented (1) In the part of the lipid region is allocated for the phospholipid bilayer and organelle membranes of the cell. This consist of the fatty acid side chains that have repeated the moieties of CH<sub>2</sub>- and CH<sub>3</sub>- stretching vibration. (2) Protein region is designated the amide bonds of amino acids binding in proteins, and the peptide bond that provides the stretching vibration of amide I and bending vibration of amide II. (3) The region of nucleic acid is given for phosphodiester bonds binding to form DNA/RNA. Accordingly, the sensitized TF-1 cells of Ruxolitinib than Tofacitinib in the JAK/STAT pathway control can be observed and represent the FTIR spectrum. On the biological, the JAK/STAT pathway controls crucial cellular processes<sup>25</sup>. Ruxolitinib withdraw phosphorylated STAT3 and stimulated caspase-3 cleaving, enhanced apoptosis, and inhibited tumor growth<sup>26</sup>. As though, the inhibitors induced autophagosome accumulation and reduced the IL-6, IL-18, JAK2, TYK2, and AKT gene expression in multiple myeloma cells<sup>27</sup>. In previous publications, Han et al. offered the western blot result of Ruxolitinib treatment using ovarian cancer cells and explained the inhibiting of STAT3 phosphorylation<sup>28</sup>. For Tofacitinib, drug effect in JAK/STAT signaling inhibition as an anti-myeloma therapeutic. The result of western blotting demonstrates that decrease in STAT3 phosphorylation after treatment with 1  $\mu$ M Tofacitinib<sup>29</sup>. *In Vivo*, Tofacitinib represses JAK-STAT pathways by downregulating the phosphorylation of STAT1, STAT3, STAT4, and STAT5 also decreases the expression of interferon-regulated and metalloproteinase genes in rheumatoid arthritis disease<sup>30</sup>.

## Conclusions

The study revealed that FTIR microspectroscopy and PCA analysis represent methods for classifying the biochemical pattern of untreated and treated TF-1 cells. The absorbance spectra of C-H lipids, C=O amide I protein, and the P=O phosphodiester bond from nucleic acids were detected. Possibly, Ruxolitinib and Tofacitinib treated cells induced the modifications of secondary protein conformation, stimulated lipid accumulation, and induced protein phosphorylation. These conclusions imply that FTIR can be a prospective tool for analyzing individual cellular response patterns in drug-treated cells at the molecular level.

## Materials and Methods

### 2.1 Cell culture of TF-1 cell line

The human erythroleukemia TF-1 cells (ATCC CRL-2003, Manassas, VA, USA) were grown in a complete RPMI-1640 medium (Gibco, Thermo Fisher Scientific Inc., Waltham, Massachusetts, USA) supplemented with fetal bovine serum (FBS) (10% v/v) (Gibco), penicillin (100 U/mL), streptomycin (100 µg/mL) (Gibco) and GM-CSF (2 ng/mL) (Sigma-Aldrich, Merck KGaA, Darmstadt, Germany). Cells were incubated at 37 °C in a humidified incubator including CO<sub>2</sub> (5% v/v), and air (95% v/v).

### 2.2 Cytotoxicity

Tofacitinib and Ruxolitinib (Sigma-Aldrich) in dimethyl sulfoxide (DMSO) (Sigma-Aldrich) towards the TF-1 cells were determined using the PrestoBlue assay. The cell suspensions with a density of 50,000 cells/well were in a 96-well microplate seeding and 37 °C incubating overnight. After treatment with the drugs, the cells were 72 h incubating time. Subsequently, the cells were added to the PrestoBlue reagent (10 µL) (Invitrogen, Thermo Fisher Scientific Inc., Waltham, Massachusetts, USA), and incubated at 37 °C for 1 h. Finally, the absorbance of the resorufin was measured at 570 nm compared to the vehicle control by a microplate reader (Infinite M200 microplate reader, Tecan, Männedorf, Switzerland). The experiment was performed in triplicate independent experiments (n=9).

### 2.3 *Molecular Docking*

The crystal structure of JAK1 (PDB ID: 3EYG) and JAK2 (PDB ID: 3FUP)<sup>14,31</sup> were obtained from the Protein Data Bank (PDB). The 3D structures of the drugs (Ruxolitinib and Tofacitinib) were downloaded in SDF format from the ZINC database. All docking tests were performed by GOLD docking software version 2020.1. The docking protocols of each system were set as 12 Å for sphere docking and GOLD score and ChemScore (rescore) for the scoring function. Then, docking into the ATP-binding pocket with 100 docking poses occurred. The binding between proteins and drugs was visualized using the Discovery Studio 2020 (Accelrys Inc.) and the UCSF Chimera package.

### 2.4 *Sample preparation for S-FTIR*

The TF-1 cells density of 300,000 cells/well was seeded in a 24-well microplate and incubated overnight at 37 °C. Afterward, the cells were replenished with a medium without drugs or a medium containing 2-fold concentrations of Tofacitinib or Ruxolitinib for a half-inhibitory concentration. After incubation for 72 h, cells were harvested by centrifuge at 300 g for 5 min. The pelleted cells were suspended and washed in NaCl (0.9% w/v) two times and then cells were fixed with formaldehyde (4% v/v) at 25 °C for 30 min. After decanting with formaldehyde, cells were washed three times and re-suspended with sterile distilled water (20 µL). The re-suspended cells (2 µL) were dropped onto 22 m-diameter × 1 mm-thickness calcium fluoride IR (CaF<sub>2</sub>) windows for monolayer formation, then vacuum-dried and stored in a desiccator until spectra were acquired from FTIR analysis.

### 2.5 *Synchrotron Fourier-transform Infrared spectroscopy*

The S-FTIR experiments were accomplished at the BL4.1 Infrared Spectroscopy and Imaging (ISI), Synchrotron Light Research Institute (SLRI), Nakhon Ratchasima, Thailand. Samples were examined in the transmission mode of measurement using a Photon Energy range of 0.01-0.5 eV with a 36X Schwarzschild Objective, a Bruker Vertex 70 spectrometer coupled to a Bruker Hyperion 2000 microscope (Bruker Optics Ltd., Ettlingen, Germany) and a 100-micron narrow band mercury-cadmium-telluride (MCT) detector cooled with liquid nitrogen. Infrared spectra of samples were collected in the spectral range between 3,800-1,000 cm<sup>-1</sup> using a 10X10 µm square aperture with a spectral resolution of 6 cm<sup>-1</sup> in 40 to 100 scans. The instrument control

and spectral achievement were performed by OPUS 7.2 software (Bruker Optics Ltd., Ettlingen, Germany) and evaluated in the spectral range of 3,000–2,800 and 1,800–1,000  $\text{cm}^{-1}$  for each sample group for PCA by Unscrambler 10.4 software (CAMO, Oslo, Norway). The absorbance of interesting molecules during vibrational modes was identified by spectral secondary derivative analysis. The absorbances of C-H stretching of lipids were detected between 3,000–2,800  $\text{cm}^{-1}$ . The absorbances between 1,700–1,500  $\text{cm}^{-1}$  from C=O stretching protein amide I and P=O phosphodiester bond from nucleic acids were detected in the absorbance of 1,300–1,000  $\text{cm}^{-1}$ .

## 2.6 Statistical analysis

The  $\text{IC}_{50}$  values data are articulated as mean  $\pm$  standard error of the mean (SEM). In the cytotoxicity experiments, significant differences were determined by comparing each treatment with the independent T-Test.  $P < 0.05$  was counted as indicative of a statistically significant difference.

**Abstract**

**Background and Objectives:** Natural products have proven to be a valuable source for the discovery of new candidate drugs for cancer treatment. This study aims to investigate the potential therapeutic effects of "Kerra™", a natural extract derived from a mixture of nine medicinal plants mentioned in the ancient Thai scripture named "Takxila Scripture", on HCT116 cells. **Materials and Methods:** In this study, the effect of the Kerra™ extract on cancer cells was assessed through cell viability assays. Apoptotic activity was evaluated by examining the apoptosis

characteristic features. Proteomics analysis was conducted to identify proteins and pathways associated with the extract's mechanism of action. The expression levels of apoptotic protein markers were measured to validate the extract's efficacy. Results: The Kerra™ extract demonstrated a dose-dependent inhibitory effect on the cells, with higher concentrations leading to decreased cell viability. Treatment with the extract for 72 hours induced characteristic features of early and late apoptosis, as well as cell death. LC-MS/MS analysis identified a total of 3,406 proteins. The pathway analysis revealed that the Kerra™ extract stimulated apoptosis and cell death in colorectal cancer cell lines and suppressed cell proliferation in adenocarcinoma cell lines through the EIF2 signaling pathway. Upstream regulatory proteins including cyclin-dependent kinase inhibitor 1A (CDKN1A) and MYC proto-oncogene, bHLH transcription factor (MYC), were identified. The expression of caspase 8 and caspase 9 was significantly elevated by the Kerra™ extract compared to the chemotherapy drug, Doxorubicin (Dox). Conclusions: These findings provide strong evidence for the ability of Kerra™ extract, to induce apoptosis in HCT116 colon cancer cells. The extract's efficacy was demonstrated by its dose-dependent inhibitory effect, induction of apoptotic activity, and modulation of key proteins involved in cell death and proliferation pathways. The study highlights the potential of Kerra™ as promising therapeutic agents in cancer treatment.

**Keywords:** traditional herbs; LC-MS/MS; colorectal cancer; caspase-8, caspase-9; CDKN1A; MYC

## 1. Introduction

The utilization of natural products for cancer treatment has gained prominence in recent years. Natural products have proven to be a valuable source for the discovery of new candidate drugs for cancer treatment. For example, Curcumin, a compound found in rhizomes of *Curcuma longa* (turmeric), has been shown to have antiproliferative and proapoptotic effects on various cancer cells including colon cancers, prostate cancers, and lung cancers [1-3]. Epigallocatechin gallate, a compound found in green tea, has been shown to inhibit the growth of various types of cancer cells such as ovarian cancers, head and neck Cancer [4,5]. Interesting,

combination of curcumin and epigallocatechin gallate exhibited potential anti-cancer activity inducing apoptosis in the various cancers [6]. Researchers are exploring compounds derived from natural products as potential alternatives for cancer treatment. One significant advantage of using crude natural products is their ability to target multiple pathways within cancer cells simultaneously. Cancer cells often activate multiple survival pathways, and natural products with their complex phytochemicals can effectively target these pathways, surpassing the effectiveness of single compounds that only focus on specific protein marker. Natural products typically contain various phytochemicals that can work together synergistically, resulting in a more potent therapeutic effect. This synergy adds to their potential as valuable treatments. Besides, utilizing crude herbal products for alternative cancer treatment offers several benefits, such as the ability to target multiple pathways, cost-effectiveness, and the combined effects of different compounds working together. These factors emphasize the importance of natural products in developing new and effective cancer treatments.

“Takxila”, with the commercial name of “Kerra™ ” from the ancient Thai scripture named “Takxila Scripture” was mixed of nine-ingredient medicinal plants such as *Pterocarpus santalinus*, *Santalum album*, *Momordica cochinchinensis*, *Citrus aurantiifolia*, *Dregea volubilis*, etc [7]. Each of these plants mentioned in the scripture has demonstrated significant potential in cancer therapeutics [8-12]. In addition, Kerra™ can inhibit inflammatory response and two enzymes in severe acute respiratory syndrome coronavirus 2 including main protease and RNA-dependent RNA polymerase [7]. However, while the mixture of these medicinal plants adheres to the "Takxila" formula for alternative cancer treatment, there remains a big knowledge gap in understanding its efficacy. In cancer therapeutic aspects, the natural process of cell death known as apoptosis is usually altered in several signaling pathways [13]. Therefore, the discovery of new traditional herbs with apoptotic activity can be an effective approach for treating cancer.

Apoptosis, or programmed cell death, plays a crucial role in the development and maintenance of tissue and organ health in multicellular organisms [14]. Caspases play a crucial role as key regulators of apoptosis and are part of the cysteine endo-protease family that mediates cell death and inflammation. In

mammals, caspases have been classified based on their well-defined biological functions in apoptosis, with caspase-3, -6, -7, -8, and -9. The biological process of caspase-mediated apoptosis involves two primary signaling pathways: intrinsic and extrinsic. Caspase-8 mediates the extrinsic pathway, while caspase-9 initiates the intrinsic pathway. Additionally, caspase-8 and -9 exert regulatory roles by activating downstream effector caspases, such as caspase-3, -6, or -7, which are responsible for stimulating various cellular apoptotic responses[15]. The apoptosis process helps to maintain a balance between cell division and cell death, by removing damaged or abnormal cells. In the context of cancer, apoptosis is an important consideration for therapeutic strategies [13]. Cancer cells are characterized by uncontrolled cell division and evasion of normal cell death mechanisms, these results in the growth of tumors. As a result, inducing apoptosis in cancer cells has been explored as a therapeutic approach. Generally, chemotherapy by using Doxorubicin (Dox) and radiation therapies often aim to induce apoptosis in cancer cells by causing DNA damage and triggering intrinsic apoptotic pathways, or by targeting specific pathways that regulate apoptosis [16,17]. However, it is important to note that resistance to apoptosis-inducing treatments can develop over time in cancer cells, reducing their efficacy. Additionally, non-cancerous cells or normal cells can also be affected, leading to adverse effects. Hence, traditional medicine utilizing various herbal remedies with potential apoptotic activity may provide an opportunity for alternative cancer treatment.

Proteomics analysis is a powerful tool that allows the comprehensive analysis of the entire protein complement of cells. To clarify the beneficial and adverse effects of these extracts, proteomics experiments are strongly required to evaluate their impact on cell lines or animal models. Proteomics has found extensive application in studying cellular responses and biochemical pathways concerning various natural products, such as diterpenoids from *Rabdosia rubrescens*, sesquiterpenoids from *Curcuma aromatica*, and iridoid glycosides from *Gardenia jasminoides* [18-20]. By analyzing the changes in protein expression, proteomics can provide a detailed understanding of the molecular mechanisms underlying the effect of external stimulants on cellular processes such as apoptosis [21,22]. In addition, proteomics analysis can be combined with other techniques, such as transcriptomics,

metabolomics and lipidomics, to provide a more complete picture of the molecular mechanisms underlying the effect of the external stimulants on cellular processes.

## 2. Materials and Methods

### 2.1 Kerra™ extract preparation and cell cytotoxicity evaluation

The Kerra™ was extracted by shaking the capsule powder in 95% ethanol at a ratio of 1:100 (w/v) for 24 hours at 37 °C. The extracted was filtered with the paper filter (Whatman, No. 41, pore size 20-25 µm) and concentrated at 40 °C by rotary evaporator (Buchi rotavapor R-210, BÜCHI Labortechnik, Flawil, Switzerland). Finally, the concentrated extract was dissolved in 100% DMSO (Merck KGaA, Germany). The human colorectal carcinoma cell line (HCT116) was bought from the American Type Culture Collection (ATCC; CCL-247). The cells were cultured in the complete growth media of modified McCoy's 5A medium (Gibco, Thermo Fisher Scientific Inc., Waltham, Massachusetts, USA) with 10% v/v fetal bovine serum (Gibco) and 1% v/v Antibiotic Antimycotic solution (100 units penicillin, 0.1 mg streptomycin and 0.25 µg/mL amphotericin B) (Gibco). Cultured cell lines were incubated at 37 °C and 5% CO<sub>2</sub>. Cell cytotoxicity was determined based on MTT assay by the mitochondria dehydrogenase enzyme and cofactor reduction activity with the 3-[4, 5-Dimethylthiazol-2-yl]-2,5-Diphenyltetrazolium Bromide (MTT; Merck KGaA, Germany) forming purple color crystals of formazan. The density of HCT116 was seeding 1×10<sup>4</sup> cells/well or 1×10<sup>5</sup> cells/mL in 96 wells plate and left in an incubator for 24 hours for cell adherence. The cells were treated with samples for 72 hours in nine concentrations of two-fold serial dilution Kerra™ extract (5-0.020 mg/mL). The 0.1% DMSO was used as control condition. Cell cytotoxicity was assessed by measuring the absorbance at 570 nm and calculating the percentage of cell survival rate. Following from this calculation:

$$\text{Cell viability (\%)} = \text{Mean OD}_{\text{sample}} / \text{Mean OD}_{\text{blank}} \times 100 \quad [23].$$

The experiments were conducted in three replications (n=3). The 50% cell proliferation inhibitory concentration (IC<sub>50</sub>) was analyzed on a nonlinear regression dialog using GraphPad Prism 8 software (GraphPad Software Inc., San

Diego, California, USA). The resulting graph was presented in mean  $\pm$  standard deviation (SD) of cell viability compared with the control.

## 2.2 Investigation of apoptotic events in HCT116 cells

The detection of apoptosis in HCT116 cells was conducted using the Muse™ Annexin V & Dead Cell Kit (MCH100105, EMD Millipore Co., , USA) following the manufacturer's guidelines [24]. Briefly, the cells were seeded in a 6-well plate at a density of 300,000 cells per well and allowed to incubate overnight at 37 °C. The experiments consisted of three experimental group including negative control (0.1% DMSO), positive control (0.1  $\mu$ M Dox) and Kerra™ extracts (73  $\mu$ g/mL). The cells were incubated in a 5% CO<sub>2</sub> incubator with 95% humidity for 72 hours. The treated cells were harvested, trypsinized and the commercial kit protocol was applied. The treated cells were harvested using trypsinization and resuspended in a fresh culture medium. The cells were then stained with the Muse® Annexin V & Dead Cell Kit (Luminex Corp., USA) and incubated in the dark at room temperature for 20 minutes. Fluorescence intensity was measured using flow cytometry with the Muse™ Cell Analyzer (Merck, Germany). The stained cells were categorized into four groups: live cells (annexin V-/7-AAD-), early apoptotic cells (annexin V+/7-AAD-), late apoptotic cells (annexin V+/7-AAD+), and necrotic cells (annexin V-/7-AAD+). The apoptotic values were expressed as percentages of healthy, apoptotic, and dead cells in the negative control, positive control, and Kerra™ extract conditions.

## 2.3 Sample preparation for label-free proteomics analysis

The treated HCT116 cells were prepared for proteomics using previously published protocol with minor modifications [25,26]. Briefly, the cells were lysed on-ice using a probe tip sonication at a frequency of 20 kHz and 80% amplitude for 2 seconds on, and 3 seconds off at the total of 15 seconds in 200  $\mu$ L lysis buffer (0.2% TritonX-100, 2 mM TCEP, 5 mM sodium chloride, 10 mM HEPES-KOH, pH 8.0) with protease inhibitor cocktail. The protein solution was

collected by centrifugation at 15,000g for 30 minutes and subsequent to ice-cold 15% TCA/acetone precipitation (1:5 v/v) for 16 hours. After precipitation, the pellet protein was reconstituted in 0.5% RapiGest SF (Waters, UK), 5 mM NaCl in 5 mM ammonium bicarbonate. A total of 40 µg of protein were subjected to gel-free based digestion. Reduction sulfhydryl bonds by using 1 mM TCEP in 5 mM ammonium bicarbonate at 56 °C for 1 hour and alkylation of sulfhydryl groups by using 4 mM IAA in 5 mM ammonium bicarbonate at room temperature for 40 minutes in the dark. The solution was cleaned-up by desalting column (Zeba™ Spin Desalting Columns, 7K MWCO, 0.5 mL, ThermoFisher). The flow-through solution was enzymatically digested by Trypsin (Promega, Germany) at ratio 1:40 (enzyme: protein) ratio and incubated at 37°C for 6 hours. The tryptic peptides were dried and stored at -20°C until LC-MS/MS analysis.

#### 2.4 LC-MS/MS configurations for proteomics analysis

The proteomics analysis was performed using a high-resolution SciEx 6600+ TripleTOF system (AB-Sciex, Concord, Canada) coupled with a nanoLC system, the UltiMate 3000 LC System (Thermo Fisher Scientific, USA), followed by previously publications with minor modifications [27]. Briefly, the dried tryptic peptides were reconstituted with 0.1% formic acid and 1.2 µg of protonated peptides were subjected to the nanoLC system. The mobile phases consisted of A) 0.1% formic acid in water and B) 95% acetonitrile with 0.1% formic acid. The samples were directly loaded onto a C18-reverse phase column (2 mm, 75 µm x 15 cm) and separated over a 155-minute period at a constant flow rate of 300 nl/min. The mass spectrum was acquired in data-dependent acquisition mode, with full scans over a mass range of 400-1600  $m/z$ . The top 30 most abundant peptide ions with charge states ranging from 2 to 5 were selected for fragmentation. The dynamic exclusion duration was set at 18 seconds. The raw MS files were annotated with referenced protein sequences using the Paragon algorithm by ProteinPilot software [28]. The reviewed database used for the Paragon algorithm was assembled in FASTA format and retrieved from UniprotKB (<https://www.uniprot.org>) on October 21, 2022 (species: *Homo sapiens*) [29].

## 2.5 Protein data and pathway enrichment analysis

To reduce the variability in the protein dataset, The normalization of protein intensity was performed using the NormalizerDE [30], with quantile normalization applied to the relative expression data analysis after adding "1" to all expression values. To ensure high confidence data, only proteins identified with an FDR  $\leq 1\%$  and  $\geq 10$  peptides/protein were considered for the confidential protein list. The differentially expressed proteins were shown in volcano plot using a negative natural log of the  $p$ -values plotted against the base2 log values of the change in each protein between the Kerra™ extract (n=3) and negative control group (n=3). The effect of Kerra™ extract on pathway signaling cascade in HCT116 cells were analyzed using Ingenuity Pathway Analysis (IPA). All differentially expressed proteins were imported to the core analysis and analyzed to define the significantly changed protein signaling pathways and upstream regulators . The detailed procedures for IPA analysis and its parameters are described in previously report [31]. The analysis was performed by comparing all changed proteins against known canonical pathways within the IPA database (accessed on 18 May 2023). The activation and deactivation state of pathways and upstream regulator (any protein that can affect the expression of another protein) was analyzed based on the all differentially expressed proteins and adj.  $p$ -value ( $z$ -score). Major signal transduction pathways were reconstructed according to IPA results. Acceptable upstream regulator required to had  $z$ -score  $\geq 1.5$  and  $p$ -value  $< 0.01$ .

## 2.6 Immuno-based early apoptosis protein quantification

The level of apoptotic protein markers was measured using the MILLIPLEX® early apoptosis magnetic bead kit (48-669MAG). The levels of active Caspase-8 (Asp384) and active Caspase-9 (Asp315) were quantitated based on Luminex® xMAP® technology. Different passages of HCT116 cells were used in these experiments to confirm apoptotic events in the cells. The cells were cultured according to the specified protocols. Following treatment with Kerra™ extract at IC<sub>50</sub> for 72 hours, the cells were washed with ice-cold buffered saline and disrupted with 0.3 mL of 1X MILLIPLEX® Lysis Buffer containing a protease inhibitor cocktail. To obtain lysed cells, the reaction was incubated at 50°C for 10 minutes with manual

mixing. The supernatant was collected by centrifugation at 14,000g at 16°C for 30 minutes. The protein concentration was measured using the BCA protein assay and adjusted with PBS to a concentration of 2 µg/µL. Prior to the experiment, the protein solution was further diluted in PBS at a 1:4 (v/v) ratio, resulting in a final concentration of 0.5 µg/µL. A total of 20 µL (10 µg) of the protein solution was subjected to the assay. For the magnetic beads, biotin-labeled detection antibody, streptavidin-PE, normalizing control proteins, and MILLIPLEX® cell lysates were prepared according to the manufacturer's instructions without any modifications. The efficiency and accuracy of immune-based reactions were qualified before the experiment. A549 cells stimulated with 5 µM camptothecin cell lysate were used as a positive control to confirm the expression profile of these apoptotic proteins, while HeLa cells treated with lambda phosphatase served as the negative control (no apoptotic characteristic cells) [32]. The quantification of protein levels was reported as the median fluorescence intensity (MFI) value along with the standard deviation, based on two biological replicate experiments and two replicate wells.

## 2.7 Statistical analysis

For the pairwise comparisons in proteomics analysis, a One-way analysis of variance (one-way ANOVA) at protein-level analysis with two multiple testing correction methods including the Bonferroni correction and the Benjamini and Hochberg FDR-correction was performed by ProteinPilot™ Software. For pathway analysis, A right-tailed Fisher's exact test was used to calculate the significance of pathways and upstream regulator [33].

## 3. Results

### 3.1 Cell cytotoxicity

The cytotoxicity effect of Kerra™ extraction demonstrated the anti-cancer property. The extract exhibited a dose-dependent inhibitory effect as the concentration increased. After treated 72 hours, the viability of the HCT116 cells had slightly decrease the cell viability at a concentration of 39.06 µg/mL and completely inhibited from 156.25 to 5000 µg/mL (Figure. 7).

**Figure 7** Cytotoxicity effect of Kerra™ extracts against HCT116 cells after 72 hours of exposure using MTT assay at the concentration ranging from 5 - 0.020 mg/mL in logarithmic scale.

The  $IC_{50}$  value of the Kerra™ extract was determined to be  $72.96 \pm 5.41$   $\mu\text{g/mL}$ . In comparison, the positive control, Dox, exhibited an  $IC_{50}$  value of  $0.059$   $\mu\text{g/mL}$ . These findings clearly indicate that the Kerra™ extract significantly affected the proliferation of HCT116 cells.

### 3.2 Kerra™ extract promotes apoptosis in HCT116 cells.

Flow cytometry was used to determine the apoptotic potential of Kerra extract, allowing the identification of healthy, early apoptotic, late apoptotic and death cells. To investigate the apoptotic effect, the cells were treated with the  $IC_{50}$  concentration of Kerra extract ( $73$   $\mu\text{g/mL}$ ). The cell population profiles after treatments with negative control (0.1% DMSO), positive control ( $0.059$   $\mu\text{M}$  Dox), and Kerra extract ( $73$   $\mu\text{g/mL}$ ) were shown in Figure 8A, 8B and 8C, respectively.

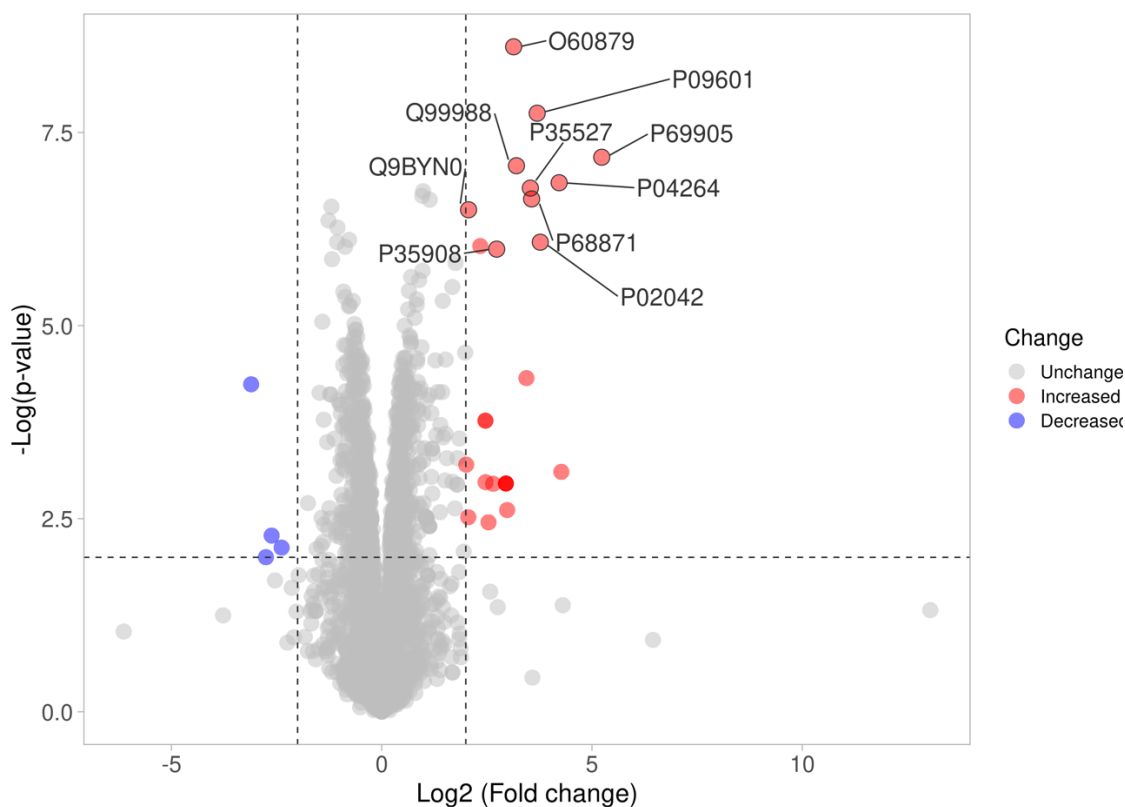

**Figure 8** Apoptosis cell characteristic analysis using Muse™ Annexin V assay. Two-dimensional diagram of viability and Annexin V-position cells in negative control (A), positive control (B) and Kerra™ extract (C) groups.

When cells treated with Kerra™ extract for 72 hours showed the early apoptosis, late apoptosis, and cell death characteristic. The cells with Kerra™ extract treatment was compared with negative control cells, there was a significant difference in the percentage of healthy and apoptotic cells ( $p$ -value<0.01). The results showed Kerra™ extract increased total apoptosis by 21.55% compared to control. For confirm the experimental assay was corrected and properly, positive control was showed the increasing apoptotic cells in comparison to negative control. These findings imply that Kerra™ extract at 73  $\mu$ g/mL can cause an increase in early and late apoptotic events in comparison to negative control cells (0.1% DMSO) in HCT116 cells.

### 3.3 Comparative proteomics analysis

In the LC-MS/MS based proteomics analysis of control and treatment conditions (IC<sub>50</sub> of Kerra™ extract), a total of 18,448 unique peptides corresponding to 3406 individual proteins were identified. Among all identified proteins between Kerra™ extracts and control (0.1% DMSO), a total of 2196 (64%) and 1210 (36%) proteins were identified in high confidence ( $\leq 1\%$  FDR,  $\geq 2$  unique peptides) and low

confidence ( $\geq 1\%$  and  $\leq 5\%$  FDR,  $\leq 2$  unique peptides), respectively (Figure 9) (supplementary data 1).

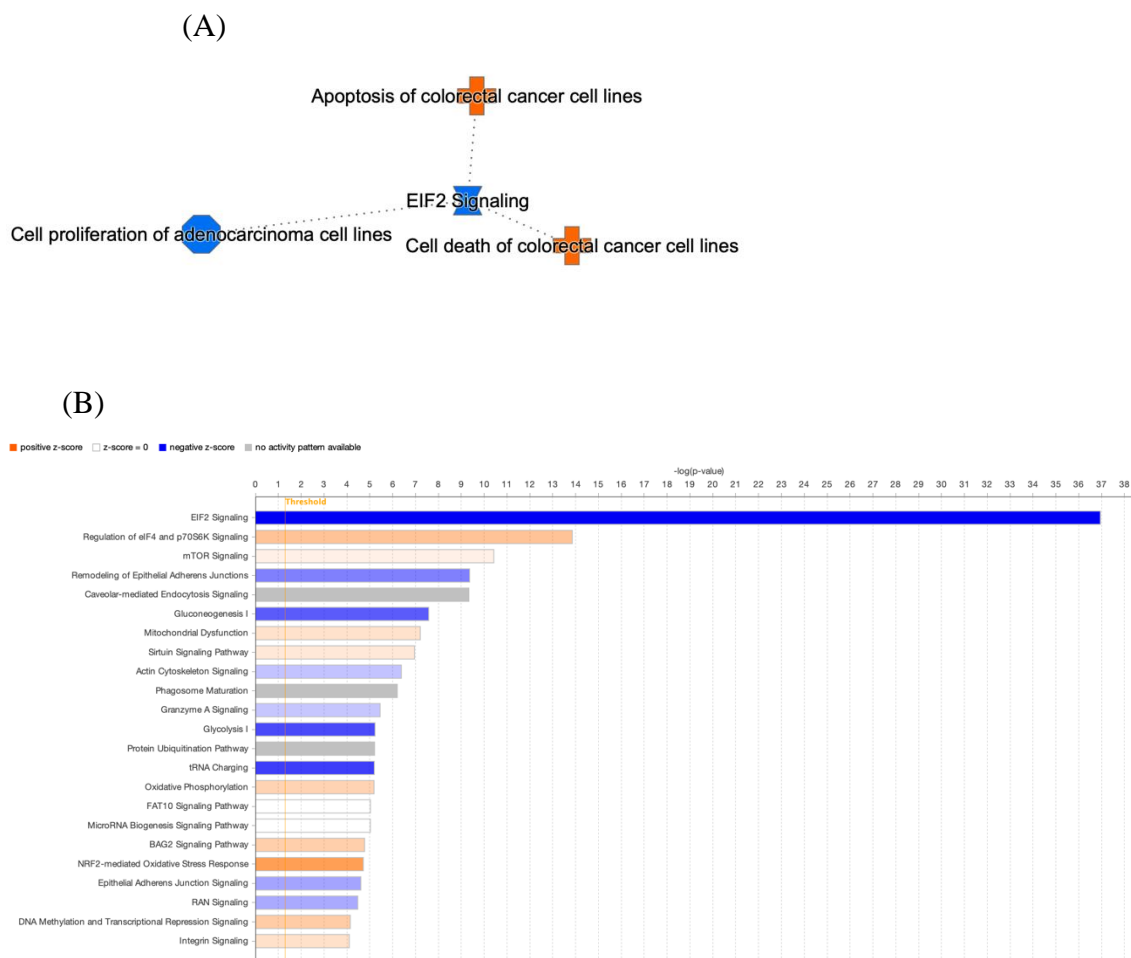

**Figure 9** Differences in proteome expression by a volcano plot. The plot shows a negative natural log of the p values plotted against the base2 log values of the change in each protein between the Kerra extract with control group (Figure 9). Significantly differentially expressed protein were chosen by  $p < 0.01$  and  $\log_2$  fold change  $> 2$ . The upregulated and down-regulated proteins are marked as red and blue dots, respectively.

### 3.4 The effect of Kerra™ extract on pathway signaling in HCT116 cells

Pathway signaling analysis of all proteome dataset in Kerra™ extract using IPA revealed various pathway were activated and inhibited. The analysis revealed Kerra™ extract stimulated apoptosis and cell death in colorectal cancer cell lines and suppressed cell proliferation of adenocarcinoma cell lines via EIF2 signaling pathway (Figure 10A).

**Figure 10** The IPA analysis revealed the identification of canonical pathways. The threshold levels were indicated by the horizontal line. A negative  $z$  score indicates pathway inhibition, while a positive  $z$  score indicates pathway activation. White (transparent) bars signify "no activity" within the pathway

For conical pathway signaling analysis, IPA revealed 9 significantly deactivated ( $z \leq -1.5$  and  $-\log(p\text{-value}) > 4$ ) and 9 significantly activated ( $z \geq 1.5$ ,  $-\log(p\text{-value}) > 4$ ) (Figure 10B). In terms of the prediction of upstream regulatory pathways in response of Kerra<sup>TM</sup> extract in HCT116 cells, there were 13 upstream regulators (Table 2). Among these regulators, cyclin dependent kinase inhibitor 1A (CDKN1A) and MYC proto-oncogene, bHLH transcription factor (MYC) exhibited the highest and lowest activation  $z$ -score, respectively.

**Table 2** Upstream protein regulators predicted to be activated (positive value of activation z-score) or Inhibited (minus value of activation z-score) in HCT116 cells after Kerra™ extract treatment.

Upstream regulator	Molecular function	Activation z-score	p-value
MYC	Transcription regulator	-1.83	1.19e <sup>-3</sup>
HIF1A	Transcription regulator	-1.75	1.45e <sup>-1</sup>
LONP1	peptidase	-1.23	1.2e <sup>-8</sup>
TLR4	Transmembrane receptor	-1	5e <sup>-3</sup>
THBS2	-	-1	1.26e <sup>-3</sup>
KRAS	Enzyme	-0.29	1.4e <sup>-2</sup>
SFN	-	-0.25	9.18e <sup>-3</sup>
SMARCA4	Transcription regulator	0	4.4e <sup>-2</sup>
NDRG1	Kinase	0.17	1.27e <sup>-2</sup>
TP53	Transcription regulator	0.78	3e <sup>-4</sup>
MXI1	Transcription regulator	1	8.3e <sup>-3</sup>
GSTO1	Enzyme	1.99	5.77e <sup>-1</sup>
CDKN1A	Kinase	2.73	8.95e <sup>-2</sup>

### 3.5 Apoptosis protein level quantification

For confirmation the apoptotic-related proteins expression of Kerra™ extract induced apoptotic event, We used the immuno-based Luminex® assay, which allows the simultaneous detection of 2 apoptotic-related proteins that are markers of the apoptotic signaling pathways. There were caspase-8 (Asp384) and caspase-9 (Asp315). We used HeLa cells treated with lambda phosphatase for negative control (unstimulated cells) and A549 cells treated with 5 μM camptothecin for positive control (apoptotic cells). The results showed the all-apoptotic marker proteins in positive control were significantly higher abundance than negative control more than 100-folds (Figure 11A). These finding confirm us, the immuno-based Luminex® assay can be used to quantify the apoptotic protein in our experiment.

**Figure 11** The level of caspase 8 and caspase 9 expression were determined. (A) The efficiency and accuracy of immune-based reactions with (black bar) and without apoptotic stimulant compound (white bar) in A549 and HeLa reference cell lines. (B) The effect of Kerra<sup>TM</sup> extract on the levels of caspase 8 and caspase 9 level in HCT116 cells was measured. The Dox-treatment group is represented by white bar, while the Kerra<sup>TM</sup> treatment group is represented by black bar. The error bars indicate  $\pm$  S.D.

The efficiency and accuracy of immune-based reactions were assessed. It was observed that camptothecin significantly increased the levels of apoptotic marker proteins, including caspase 8 and caspase 9, by more than 10-fold compared to lambda phosphatase. These findings provide strong evidence that the immune-based assay used to quantify caspase 8 and caspase 9 was reliable and valid. The expression of apoptotic protein markers was significantly elevated by the Kerra<sup>TM</sup> extract, with caspase 8 and caspase 9 exhibiting increases of more than 3.7-fold and 1.5-fold, respectively, compared to Dox (Figure 11B).

#### 4. Discussion

Interestingly, the Kerra<sup>TM</sup> extract exhibited a higher induction of late apoptosis and cell death in HCT116 cells compared to Dox at a concentration of 0.059  $\mu$ M. Our results demonstrated that under Dox conditions, the percentage of HCT116 cells exhibiting total apoptosis characteristics was 20.65% (Figure 8B). Furthermore, the apoptosis levels in HCT116 cells could be further increased by raising the Dox

concentration to 1 or 10  $\mu\text{M}$  [34]. Additionally, prolonged treatment with Dox also resulted in late apoptosis and cell death in HCT116 and MCF7 cells after an incubation period of 5 days [35]. Therefore, the observed apoptotic characteristics in these cells imply that certain phytochemical compounds present in the Kerra<sup>TM</sup> extracts have the ability to induce late apoptosis and cell death in HCT116 cells more effectively than Doxorubicin alone, specifically at this dosage. Dox is an anticancer drug widely used in chemotherapy for the treatment of various cancers[36]. It exerts its therapeutic effects by inducing various biological cellular changes, including cellular apoptosis. The effectiveness of Dox depends on both the dosage administered and the types of cells it targets[37,38]. This represents a research gap that needs to be addressed in future studies, aiming to identify the specific phytochemicals or combinations of phytochemicals responsible for inducing cell apoptosis. For confirmation apoptotic HCT116 cells can be induced by Kerra<sup>TM</sup> extracted, we done the Kerra<sup>TM</sup> extract treatment again with 2-fold higher concentration (146  $\mu\text{g}/\text{mL}$ ), the percentage of apoptotic cells also dramatically increased (data not shown). These findings suggest that the Kerra<sup>TM</sup> extract has the ability to induce cell apoptosis in HCT116 cells in a dose-dependent manner. However, the biochemical mechanisms underlying this effect are not yet fully understood, but the results of the study suggest that Kerra<sup>TM</sup> extract has potential as a therapeutic agent for colon cancer.

To gain better understanding in the effect of Kerra<sup>TM</sup> on cellular responses, studying the interaction between proteins is crucial for understanding their overall biological significance. Many proteins require interactions with specific partners to function properly. Therefore, analyzing the relationships between differentially expressed proteins is valuable in gaining insights into the integral biological roles of these proteins. To achieve this, we utilized the IPA tool to conduct network analysis, using microarray data from published literature as the basis for our investigation [39]. All the differentially expressed proteins were shown to be involved in 18 conical pathway networks. Based on the  $z$ -scores and  $p$ -values, the EIF2 signaling ( $p$ -value= $1.13\text{e}^{-37}$ ) was highest affected by Kerra<sup>TM</sup> extract treatment in the cells.

The current understanding of the upstream regulators influencing Kerra<sup>TM</sup> extracts on HCT116 cells remains limited. This study aims to enhance our

knowledge of the molecular function of Kerra™ extracts and its upstream regulators. The report emphasizes key protein regulators, such as CDKN1A and MYC. Previous studies have demonstrated that Curcumin can induce apoptosis by causing G1 cell cycle arrest in a human adenocarcinoma cell line, independently of TP53, while also simultaneously inducing CDKN1A expression [40]. Therefore, our finding revealed potential up-regulators as protein candidates for further investigation in relation to the development of Kerra™ extracts for colorectal cancer therapeutic approaches. In order to identify promising protein upstream regulators, we utilized previously obtained phytochemical data from the Kerra™ extracts [7]. We focused on the five most abundant phytochemicals: 2-methoxy-9H-xanthen-9-one, iso-rhapontigenin, Betaine, Anethole, and Eicosatetraynoic acid. To explore the interactions between these phytochemicals and upstream proteins, we employed the STITCH protein-ligand interaction tool (accessed on 21 May 2023) [41]. We discovered that betaine has a direct interaction with TLR4 (score=0.82), which is one of the candidate protein upstream regulators (Figure 12). However, the remaining four phytochemicals did not exhibit any interaction with the protein upstream regulators.

**Figure 12** Protein upstream regulators and phytochemical in Kerra™ extract interaction prediction. Ligand protein mapping was constructed from 2-methoxy-xanthen-9-one, isorhapontigenin, betaine, anethole, and eicosatetraynoic acid with the upstream regulators. The predicted interactions were shown in the connecting line.

In addition, TLR4 also have direct interaction with KRAS and TP53 which they are candidate proteins in our results too. Our results showed TRL4 also interacts with KRAS and TP53, both of which are upstream candidate proteins identified in our results. We aimed to investigate the potential of integrating proteomics data, pathway analysis, and phytochemicals from Kerra™ extracts to study chemical compounds within biological pathways. Consequently, these findings serve to support our research and provide guidance for understanding the biochemical mechanisms of Kerra™ in HCT116 cells. It is suggested that the Kerra™ extract could potentially induce apoptotic events in HCT116 cells through the TLR4.

Apoptosis, a fundamental physiological process, plays a critical role in the normal development and maintenance of multicellular organisms. In humans, the cells exhibit two primary apoptotic pathways including the intrinsic pathway, which

involves Caspase-9 activation and is triggered by mitochondrial dysfunction, and the extrinsic pathway, which involves Caspase-8 activation and is initiated by the activation of cell surface receptors [42,43]. Immuno-based protein analysis revealed that both Caspase-8 and Caspase-9 were over-expressed under Kerra™ treatment condition compared to Dox. Furthermore, the expression pattern of these proteins correlated with characteristic biochemical changes associated with apoptosis (Figure 8). Based on these findings, we can infer that the Kerra™ extract may induce apoptosis in HCT116 cells through the regulation of Caspase-8 and Caspase-9

## 5. Conclusions

Kerra™ extract from the ancient Thai scripture affected on HCT116 cell viability. In addition, the extract also induced apoptosis in the cells. The Kerra™ extracts affected to various cellular proteins and biochemical pathways. Proteomics analysis revealed that 3406 proteins were affected by the Kerra™ extracts. Using pathway analysis, we found Kerra™ extract can activated apoptosis and cell death in colorectal cancer cell lines and suppressed cell proliferation of adenocarcinoma cell lines via EIF2 signaling pathway. CDKN1A and MYC were predicted as upstream regulator in response of Kerra™ extract in the cells. Therefore, these studies provide evidence for the ability of natural extracts to induce apoptosis in HCT116 colon cancer cells, demonstrating their potential as therapeutic agents for this type of cancer. Further research is needed to fully understand the mechanisms underlying these effects and to develop safe and effective therapies.

## CONCLUSION

In conclusion, the differential effects of JAK inhibitors Ruxolitinib and Tofacitinib on myelofibrosis cancer cells study revealing Ruxolitinib is more effective due to its selective inhibition of JAK1 and JAK2 and stronger binding interactions. The synchrotron Fourier transform infrared (S-FTIR) spectroscopy technique provided valuable insights into the biochemical alterations induced by these treatments, highlighting the potential for analyzing cellular responses to cancer therapies. These findings underscore the importance of understanding the specific mechanisms of action of JAK inhibitors to enhance treatment strategies for myelofibrosis and other related malignancies.

Another study, the Kerra™ extract from traditional Thai herbs demonstrates its significant impact on HCT116 colon cancer cells, particularly in inducing apoptosis and affecting cell viability. A comprehensive proteomics analysis revealed that the extract influences cellular proteins and biochemical pathways, specifically activating apoptosis and suppressing cell proliferation via the EIF2 signaling pathway. Key proteins such as CDKN1A and MYC were identified as upstream regulators responding to the extract. These findings highlight the potential of natural extracts like Kerra™ as therapeutic agents in cancer treatment, warranting further research to elucidate the underlying mechanisms and develop safe, effective therapies for colorectal cancer.

## RECOMMENDATIONS AND FUTURE WORK

Based on the effects of JAK inhibitors on myelofibrosis cancer cell findings in the first paper. It could investigate deeper into the specific molecular mechanisms by which these JAK inhibitors exert their effects, including the downstream signaling pathways affected and the role of other cellular components in mediating these responses. Furthermore, the efficacy of additional JAK inhibitors beyond Ruxolitinib and Tofacitinib could be explored, assessing their selectivity and effectiveness against various JAK isoforms in myelofibrosis and other hematological malignancies.

Further studies in the second paper are needed to identify the specific phytochemicals in the Kerra™ extract that respond to inducing cell apoptosis regarding the detailed understanding of the upstream regulators influencing the extract's effects on HCT116 cells. Additionally, should focus on isolating these compounds and understanding their contributions to the observed biological effects. It could elucidate these mechanisms and validate the therapeutic potential of Kerra™ extract in clinical settings, particularly for colorectal cancer treatment.

## CURRICULUM VITAE

<b>NAME</b>	Jeeraprapa Siriwaseree
<b>DATE OF BIRTH</b>	22 August 1992
<b>BIRTH PLACE</b>	Kanchanaburi
<b>ADDRESS</b>	45 Village No.5, Ta Khram En Sub-district, Tha Maka District, Kanchanaburi 71130
<b>EDUCATION</b>	MS in the field of Bio-systems Sustainability, Hokkaido University, 2018 BS in Biomedical Science, Rangsit University, 2015
<b>WORK EXPERIENCE</b>	National Blood Center, Bangkok, 2015-2016 Scientist (temporary)
<b>AWARD RECEIVED</b>	The Professor Dr. Tab Nilanidhi Foundation Award in 2015 Biomedical Science in Bachelor's degree of Science, first-class honors at Rangsit University.
<b>PUBLICATION</b>	Siriwaseree, J., et al., Synchrotron Fourier Transform Infrared Microscopy Spectra in Cellular Effects of Janus Kinase Inhibitors on Myelofibrosis Cancer Cells. ACS Omega, 2022. 7. Paemane, A., et al., Mass spectrometry and synchrotron-FTIR microspectroscopy reveal the anti-inflammatory activity of Bua Bok extracts. Phytochemical Analysis, 2022. 33. Wongkhieo, S., et al., In vitro cholesterol lowering activity of Ganoderma australe mycelia based on mass spectrometry, synchrotron Fourier-transform infrared analysis and liver-spheroid bioactivity. Scientific Reports, 2023. 13. Siriwaseree, J., et al., Exploring the Apoptotic-Induced Biochemical Mechanism of Traditional Thai Herb (Kerra™) Extract in HCT116 Cells Using a Label-Free Proteomics Approach. Medicina, 2023. 59: p. 1376. Ratanabunyong, S., et al., Exploring the apoptotic effects of sericin on HCT116 cells through comprehensive nanostring transcriptomics and proteomics analysis. Scientific Reports, 2024. 14.
<b>SCHOLARSHIP</b>	the Royal Golden Jubilee Ph.D. Program between the National Research Council of Thailand (NRCT) and the Synchrotron Light Research Institute (SLRI)
